Assignment 2

1. You are required to read following chapters from https://pages.cs.wisc.edu/~remzi/OSTEP/ for upcoming 2 week lab.
    a) Introduction (Also execute and understand all code example)
    b) Processes
    c) Process API (Also execute and understand all code example)
    d) Process Termination

You need to summarize these chapters in your own language (This should be a professional summary with sections, subsections, proper indentations, highlighting new terms, use enumerated list) and in your own handwriting. All code examples should be executed. Most of these are having infinite loop, you need to modify these loops for a finite number of iterations as per input given by user. **(Submit Q1 with Assignment 3)**

2. Read and understand the **proc** virtual file system and what information can be gathered from it. Write a script to periodically collect performance monitoring data from this.

3. Learnt about fork and write code to create child process (You can use code provided by Remzi).

4. Learn how to enable and disable ASLR (Address Space Layout randomization).

5. Check whether local, global and static variables are shared among parent and child processes or not. If not, then get same or different virtual address in both child and parent process, check this with ASLR enabled and disabled.

6. Write a program to implement fork (), wait () and exit () and execv() system call.
